Equations to calculate the effect of an injection of new money:

$$\Delta D = \Delta R \times \frac{1}{r}$$

ΔR = New money

$$\Delta L = \Delta D - \Delta R$$

$$\Delta D = 3{,}000 \times \frac{1}{0.1}$$

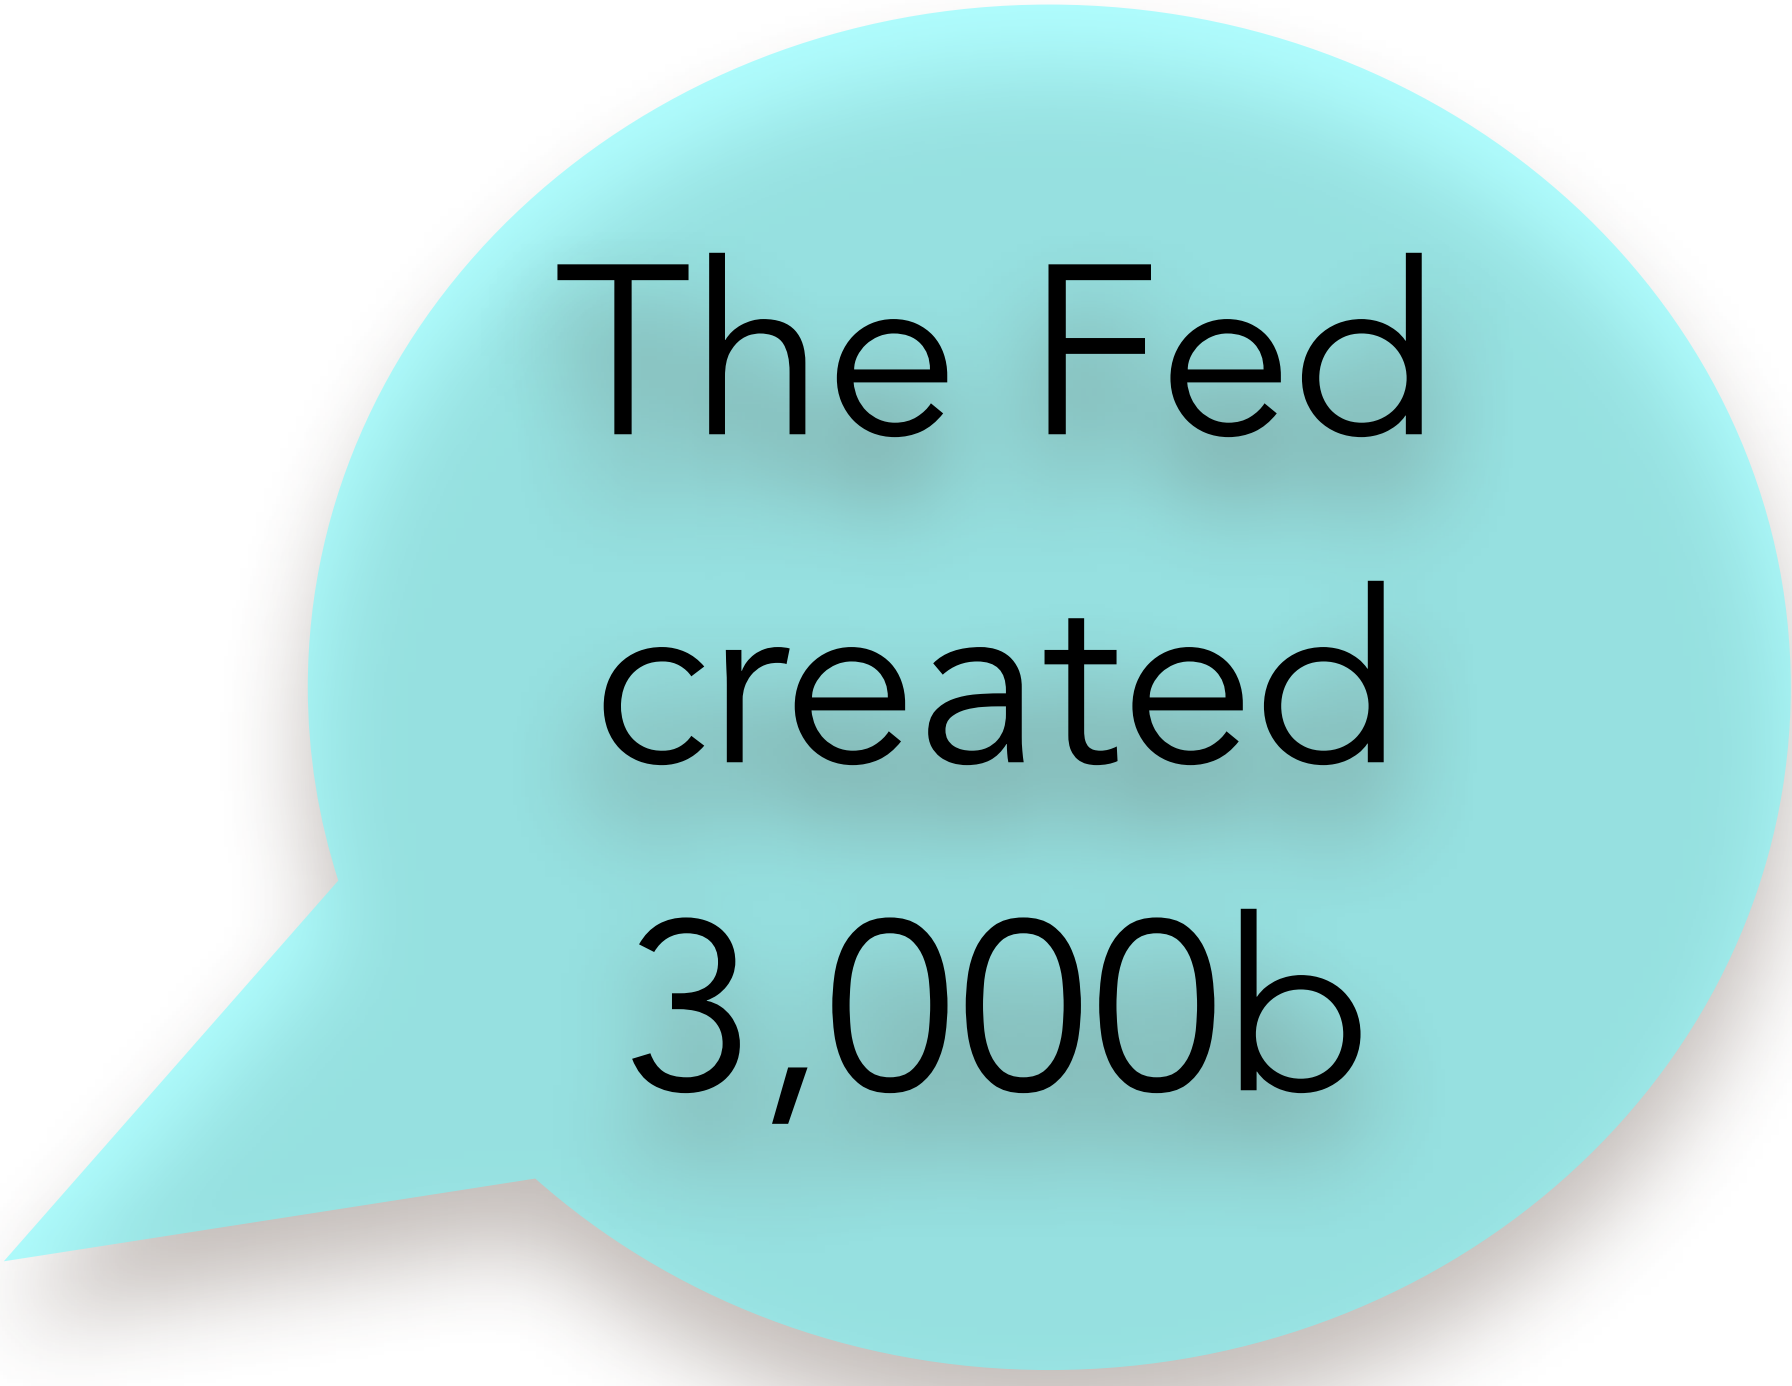
$$\Delta R = 3{,}000$$

$= 3{,}000 \times 10$

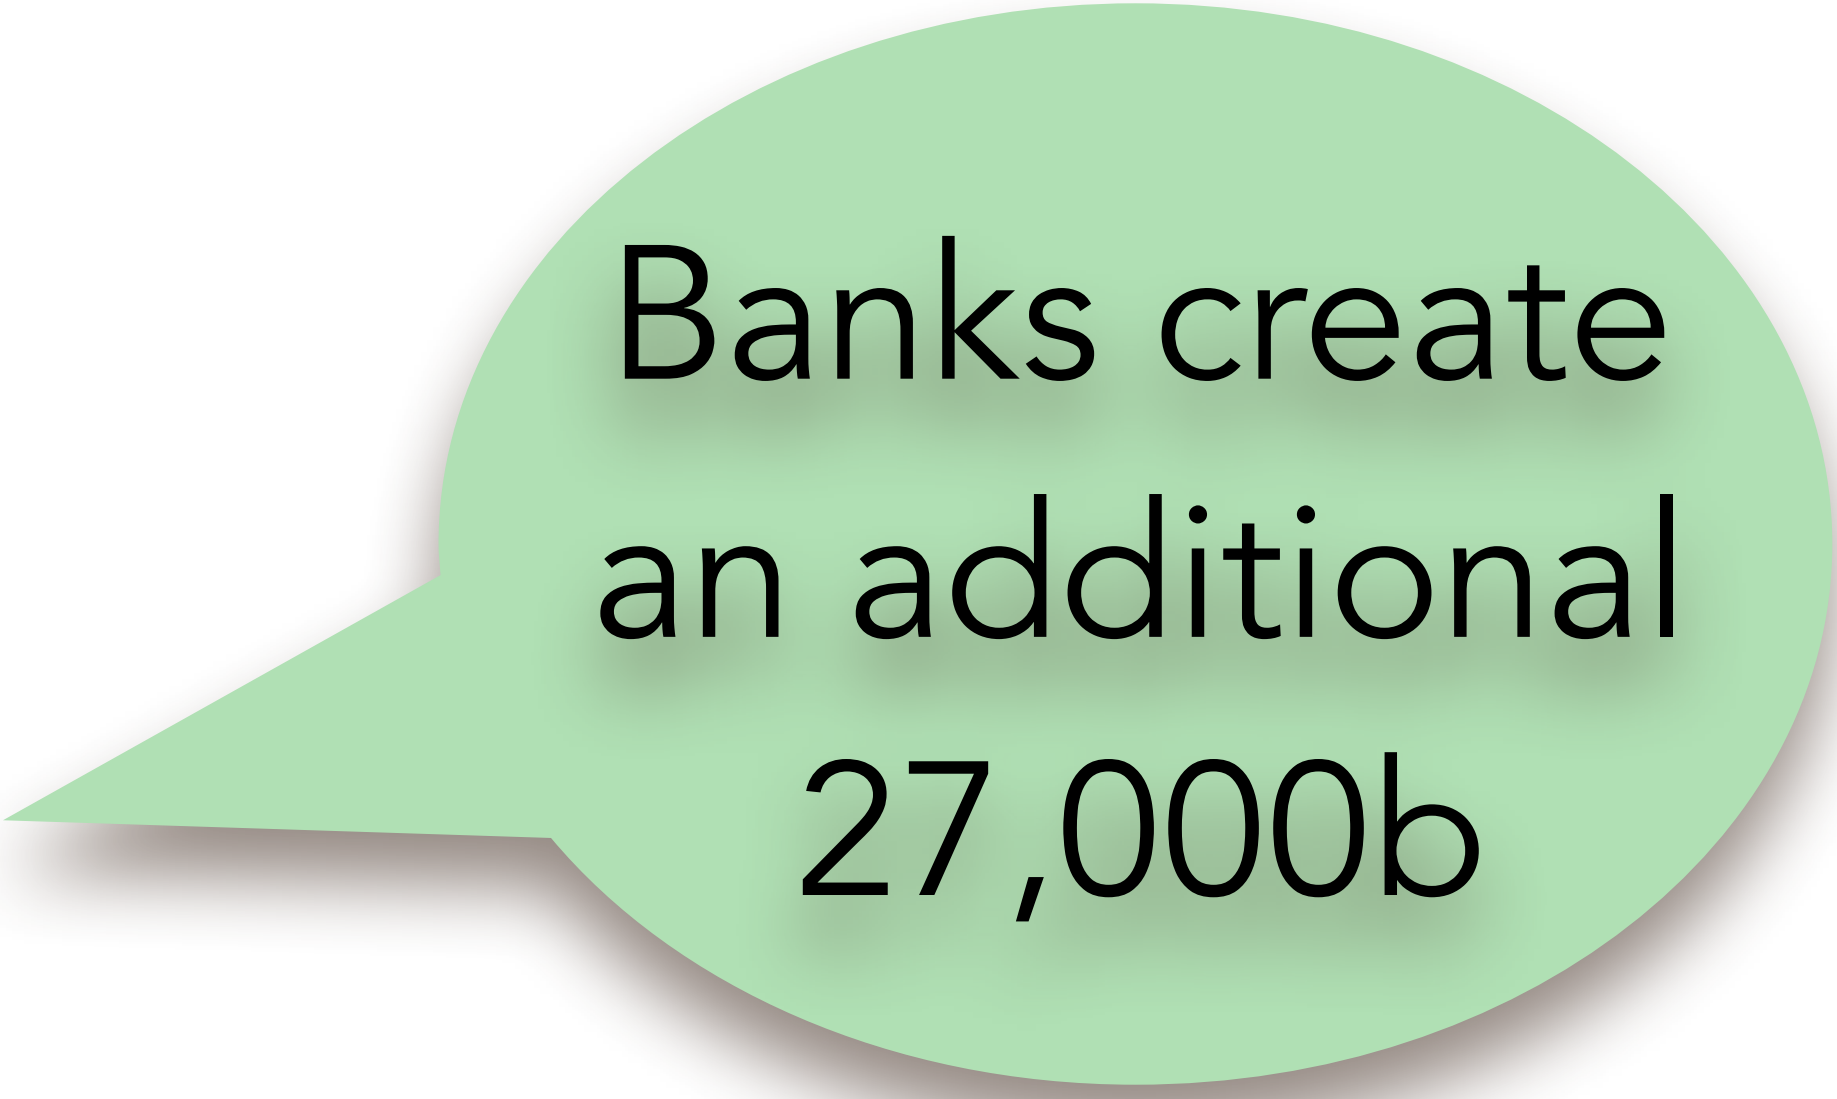
$$\Delta L = 30{,}000 - 3{,}000$$

=30,000

=27,000



The Fed
created
3,000b



Banks create
an additional
27,000b

Money Supply (M^s)= Currency outside banks + Deposits

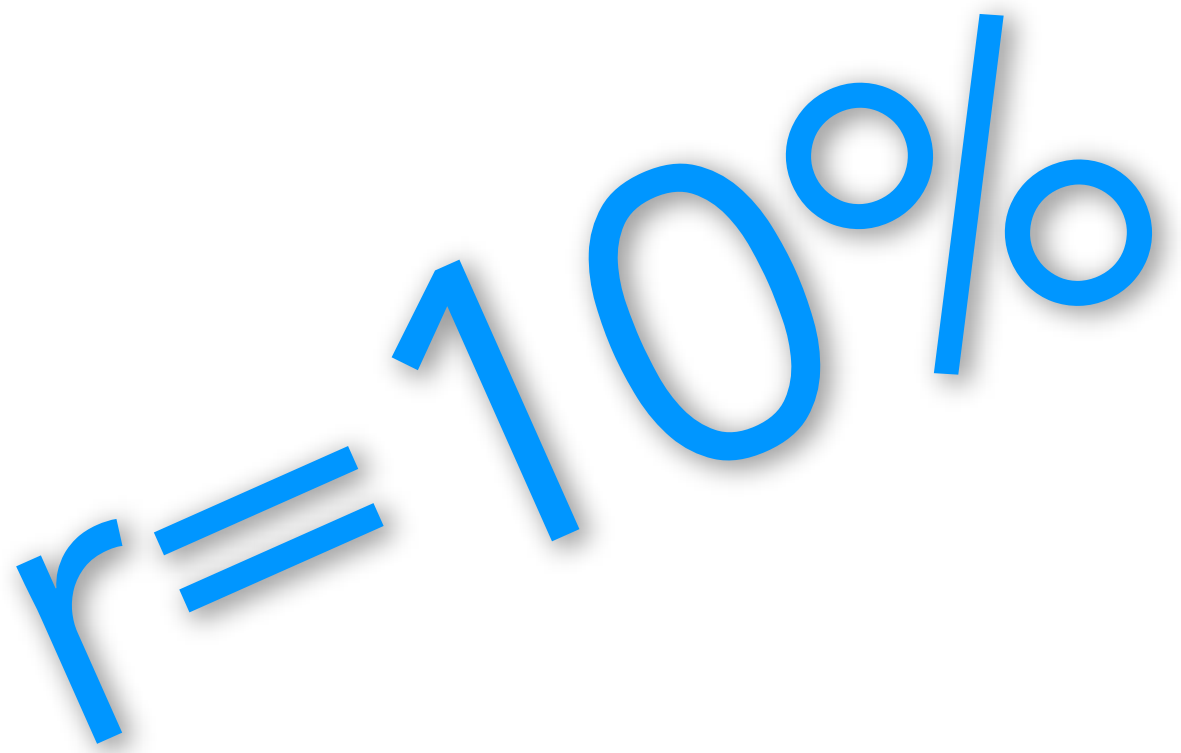
Change in the Money Supply (ΔM^s):

$$\Delta M^{s} = \Delta \text{Currency} + \Delta \text{Deposits}$$

ΔM^{s} = zero +30,000

If we **assume** that no portion of any loan "**leaks**" into **currency**

Then the change in the money supply is the same as the change in Deposits



r=10%

Equations to calculate the effect of an injection of new money:

ΔR = New money

$\Delta R = 3{,}000$

The Fed created 3,000b

$$\Delta D = \Delta R \times \frac{1}{r} \quad r=10\%$$

$$\Delta D = 3{,}000 \times \frac{1}{0.1} = 3{,}000 \times 10 = 30{,}000$$

$\Delta L = \Delta D - \Delta R$

$\Delta L = 30{,}000 - 3{,}000 = 27{,}00$

Banks create an additional

Money Supply (

banks + Deposits

Change i

): ΔM^s = ΔCurre

If we **assume** that no portion of any loan "**leaks**" into **currency**

Then the change in the money supply is the same as the change in Deposits

ΔM^s = zero +30,000
