

The multiplier with variable taxes is smaller

- The effect of an increase in G is **smaller** with **income taxes** because as income increases, the government taxes a portion of the increase in income.

$\Delta Y = \Delta G + \Delta C$; ΔC is smaller than before

- The effect of a tax cut is also **smaller** with **income taxes** because as income increases, the government taxes a portion of the increase in income.

$\Delta Y = \Delta C$; ΔC is smaller than before

The oversimplified formula
overstates the size of the multiplier

The G multiplier with variable taxes is smaller

- The effect of an increase in G is **smaller** with **income taxes** because as income increases, the government taxes a portion of the increase in income.

$$\Delta Y = \Delta G + \Delta C; \Delta C \text{ is smaller than before}$$

- The effect of a tax cut is also **smaller** with **income taxes** because as income increases, the government taxes a portion of the increase in income.

$$\Delta Y = \Delta C; \Delta C \text{ is smaller than before}$$

The oversimplified formula
overstates the size of the multiplier

Variable taxes $T = T + tY$
